APPENDIX B

CMA AND LEVELS OF SERVICE EXPLANATION

CRITICAL MOVEMENT ANALYSIS (CMA) DESCRIPTION

Level of Service is a term used to describe prevailing conditions and their effect on traffic. Broadly interpreted, the Level of Service concept denotes any one of a number of differing combinations of operating conditions which may take place as a roadway is accommodating various traffic volumes. Level of Service is a qualitative measure of the effect of such factors as travel speed, travel time, interruptions, freedom to maneuver, safety, driving comfort and convenience.

Six Levels of Service, A through F, have been defined in the 1965 *Highway Capacity Manual*. Level of Service A describes a condition of free flow, with low traffic volumes and relatively high speeds, while Level of Service F describes forced traffic flow at low speeds with jammed conditions and queues which cannot clear during the green phases.

Critical Movement Analysis (CMA) is a procedure which provides a capacity and level of service geometry and traffic signal operation and results in a level of service determination for the intersection as a whole operating unit.

The per lane volume for each movement in the intersection is determined and the per lane intersection capacity based on the Transportation Research Board (TRB) Report 212 (*Interim Materials on Highway Capacity*). The resulting CMA represents the ratio of the intersection's cumulative volume over its respective capacity (V/C ratio). Critical Movement Analysis takes into account lane widths, bus and truck operations, pedestrian activity and parking activity, as well as number of lanes and geometrics.

The Level of Service (abbreviated from the *Highway Capacity Manual*) are listed here with their corresponding CMA and Load Factor equivalents. Load Factor is that proportion of the signal cycles during the peak hour which are fully loaded; i.e. when all of the vehicles waiting at the beginning of green are not able to clear on that green phase.

Critical Movement Analysis Characteristics

Level of Service	Load Factor	Equivalent CMA
A (free flow)	0.0	0.00 - 0.60
B (rural design)	0.0 - 0.1	0.61 - 0.70
C (urban design)	0.1 - 0.3	0.71 - 0.80
D (maximum urban design)	0.3 - 0.7	0.81 - 0.90
E (capacity)	0.7 - 1.0	0.91 - 1.00
F (force flow)	Not Applicable	Not Applicable

SERVICE LEVEL A
There are no loaded cycles and few are even close to loaded at this service level. No approach phase is fully utilized by traffic and no vehicle waits longer than one red indication.

SERVICE LEVEL B
This level represents stable operation where an occasional approach phase is fully utilized and a substantial number are approaching full use. Many drivers begin to feel restricted within platoons of vehicles.

SERVICE LEVEL C
At this level stable operation continues. Loading is still intermittent but more frequent than at Level B. Occasionally drivers may have to wait through more one red signal indication and backups may develop behind turning vehicles. Most drivers feel somewhat restricted, but not objectionably so.

SERVICE LEVEL D
This level encompasses a zone of increasing restriction approaching instability at the intersection. Delays to approaching vehicles may be substantial during short peaks within the peak hour, but enough cycles with lower demand occur to permit periodic clearance of queues, thus preventing excessive backups. Drivers frequently have to wait through more than one red signal. This level is the lower limit of acceptable operation to most drivers.

SERVICE LEVEL E
This represents near capacity and capacity operation. At capacity (CMA = 1.0) it represents the most vehicles that the particular intersection can accommodate. However, full utilization of every signal cycle is seldom attained no matter how great the demand. At this level all drivers wait through more than one red signal, and frequently through several.

SERVICE LEVEL F
Jammed conditions. Traffic backed up from a downstream location on one of the street restricts or prevents movement of traffic through the intersection under consideration.

REMARKS: Alternate Route 1: Concurrant Use of All Three Vulcan Disposal Sites and Sunshine Canyon Landfill - Based on field observations, over 1,750 vehicles currently traverse through the intersection during the peak hour. Fewer turning movements occur at the intersection due to the "T" - intersection configuration. In addition, two primary movements which are complementary (i.e., NBRT/ WBLT) occur during peak hours and are non-conflicting moves. A capacity of 1,425 vph is therefore utilized.

REMARKS: Alternate Route 1: Concurrant Use of All Three Vulcan Disposal Sites and Sunshine Canyon Landfill - Based on field observations, over 1,750 vehicles currently traverse through the intersection during the peak hour. Fewer turning movements occur at the intersection due to the "T" - intersection configuration. In addition, two primary movements which are complementary (i.e., NBRT/ WBLT) occur during peak hours and are non-conflicting moves. A capacity of 1,425 vph is therefore utilized.

REMARKS: Alternate Route 2: Use of the Boulevard Pit Only and Sunshine Canyon Landfill - Based on field observations, over 1,750 vehicles currently traverse through the intersection during the peak hour. Fewer turning movements occur at the intersection due to the "T" - intersection configuration. In addition, two primary movements which are complementary (i.e., NBRT/WBLT) occur during peak hours and are non-conflicting moves. A capacity of 1,425 vph is therefore utilized.

REMARKS:

Alternate Route 3: Use of the Sheldon Pit Only and Sunshine Canyon Landfill - Based on field observations, over 1,750 vehicles currently traverse through the intersection during the peak hour. Fewer turning movements occur at the intersection due to the "T" - intersection configuration. In addition, two primary movements which are complementary (i.e., NBRT/ WBLT) occur during peak hours and are non-conflicting moves. A capacity of 1,425 vph is therefore utilized.
